Architecture comparison · 28 October 2026

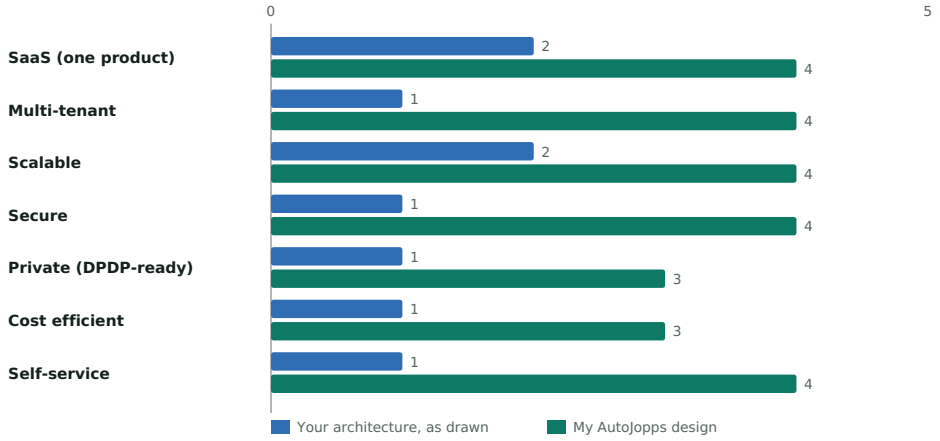

# Your architecture vs. the AutoJopps design

Is it SaaS, multi-tenant, scalable, secure, private, cheap and self-service? A direct comparison, and what to take from yours.

**Short answer**

- **Yours, as drawn, is a working prototype and a good first step, not yet a SaaS.** It is the fastest path to a live demo because the bot already works. But it has no tenant isolation, manual seat provisioning, and a cost per customer that rises with every customer.
- **Mine is a product design on paper.** It scores better on all seven questions, but nothing in it runs yet. Yours does.
- **Best plan: keep your bot, wrap it.** Put your Grok Bot behind my orchestrator as the first adapter (a “strangler” approach), then replace it portal by portal.
- **One blocker to resolve first.** A consumer Claude subscription cannot be the engine of a paid service. See issue 1 in section 2.

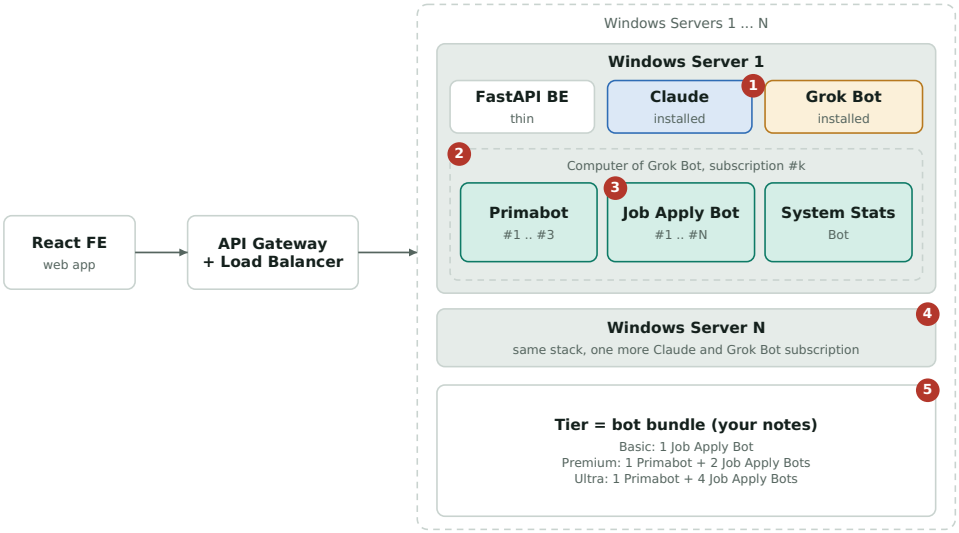

## 1. Your answers: the seven questions

Scores are my judgment on a 0-5 scale, not measurements. “As drawn” means only what your diagram and notes show; you may already have answers to some of these.

| Question | Your architecture, as drawn | AutoJopps design |
|---|---|---|
| SaaS | Partly. One web front end and API, but each customer needs a bot bundle set up on a server. | Yes. One codebase; customers are rows and entitlements, not machines. |
| Multi-tenant | Not shown. Bots on one Windows desktop share a screen, clipboard, files and browser profiles. | Yes. Per-tenant data, vault keys and a fresh browser context per run; optional silo cell. |
| Scalable | Add a server per N customers. Each new server is manual work and a new subscription. | Add cells and runners automatically; idle runners scale to zero. |
| Secure | Open question: Google and portal sessions of many users on shared machines. | Encrypted per-tenant vault, no Google password stored, single-use live-view links, audit log. |
| Private (DPDP) | Not addressed in the drawing: consent, deletion, breach flow, retention. | Designed in (consent store, deletion, minimisation). Still needs a lawyer, a notice and a breach runbook. |
| Cost efficient | Fixed cost per seat pair; see section 4. Breaks even only with many users per pair. | Variable cost per application is tracked; needs the automation ladder to reach about ₹2. |
| Self-service | Not shown. Tier = bot bundle implies someone assigns bots. | Sign-up, resume, payment, live help and tracking all by the user. |

## 2. Your architecture, annotated

Your diagram redrawn. Numbered markers are the issues explained below.

1. **Claude on each server.** Anthropic's consumer terms prohibit automated or non-human access (a bot or script) except through an API key or where explicitly permitted, prohibit account sharing and prohibit resale. A Claude subscription driving a paid service for other people is on the wrong side of this. The API under commercial terms is the supported route.
2. **Shared desktop.** Primabot, the Apply Bots and the stats bot run on one Windows computer. Tenant data and sessions sit side by side.
3. **GUI bots work one at a time per screen.** Parallelism means more desktops, so throughput is bought with machines.
4. **One more server for each step up in users.** It needs a person to buy, install, log in and pay for each pair.
5. **The tier is a bundle of bots, but the real limit is applications per day and per month.** A bot bundle does not enforce a cap; an entitlement service does.

> **Not checked.** Grok Bot's own terms, whether it has an API or only a GUI, and whether Claude computer use works on Windows Server. A secondary source says Windows is supported; I could not confirm requirements.

## 3. Side by side

| Aspect | Yours | Mine |
|---|---|---|
| Time to first demo | Days. The bot exists. | Weeks. Orchestrator, vault, live view and billing must be built. |
| Proven today | Yes, it applies to jobs. | No, design only. |
| Human help (OTP, CAPTCHA) | Remote desktop to the Grok Bot computer. | First-class state; pause, alert, resume with a signed link. |
| Isolation | Shared desktop. | Per-run context; per-tenant vault; silo option. |
| Caps and billing | By bot bundle. | Entitlement service; daily and monthly caps from Razorpay webhooks. |
| Cost shape | Fixed per seat pair, grows with users. | Mostly variable, falls as adapters get cheaper. |
| Observability | System Stats Bot (a good idea). | Event log, per-application cost, canaries. |
| Complexity | Low. | Higher; more to build and run. |
| Portal changes | Bot must cope with UI changes. | Adapters isolate each portal, with canary tests. |

### Yours: pros and cons

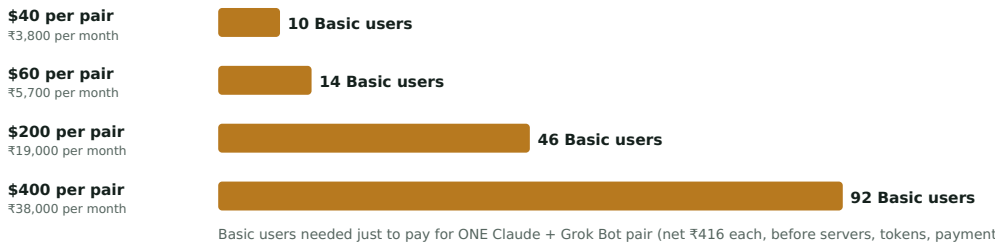

- **Pros:** it works; very simple; the Primabot + Apply Bot split is a sound pattern; the System Stats Bot is a smart health check; tiers map to a clear bundle.
- **Cons:** licence risk (issue 1, section 2); shared desktops; manual seat provisioning; fixed cost per pair; GUI-limited concurrency; no stated consent, deletion or breach handling.

### Mine: pros and cons

- **Pros:** real multi-tenancy; caps and HITL are built in; cost per application is measured; scales by cells; DPDP duties have a place to live.
- **Cons:** not built; more moving parts; Gmail scope verification and CASA assessment add weeks; the ₹2 cost target depends on moving off the GUI bot.

## 4. Cost: why the seat model is the risk

At the Basic price (₹501, about ₹416 net of GST and the gateway fee, my assumption), the question is how many users must share one Claude + Grok Bot pair before it pays for itself. Costs are your estimates ($20-30 each, up to $100-200); ₹95.1 per USD.

Break-even is the minimum. It excludes the Windows VM, any API tokens, support and the free months of users who do not pay. At Premium (about ₹831 net) the numbers halve; at Ultra (about ₹1,662) they quarter.

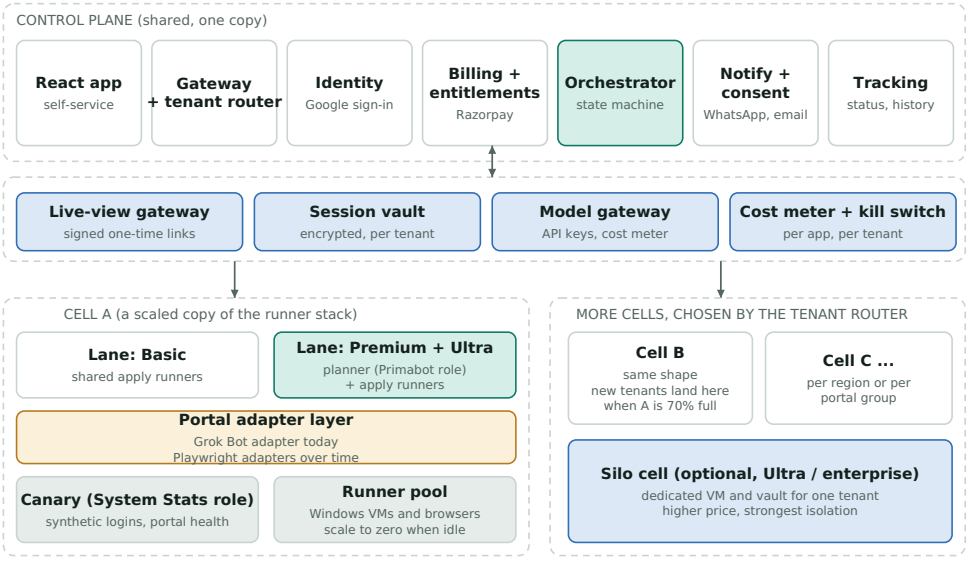

If a single pair is dedicated to one Basic user, the loss is ₹3,400 to ₹37,600 every month on every user. If a pair is shared by many users, tenant isolation (section 2, issue 2) and account sharing become the problem instead. Either way the pair cost has to come down, which is what the API and the automation ladder do.

## 5. DPDP: where each stands

| Duty | Yours | Mine |
|---|---|---|
| Notice and consent | Not shown. | Consent store; separate consent for WhatsApp. |
| Collect only what is needed | Unknown. | Resume fields minimised; Google password never stored. |
| Security safeguards | Shared desktop; session cookies of many people on one machine. | Encrypted vault, per-tenant keys, audit log. |
| Breach notification | No process shown. | Event log supports it; a runbook is still needed. |
| Erasure and withdrawal | No process shown. | Delete-my-data flow for resume, vault and logs. |
| Third-party processors | Claude, Grok, a host, undeclared. | Listed and swappable via the model gateway; needs contracts. |

The Rules were notified in November 2025 with a phased rollout of roughly 12 to 18 months; breach reports go to the Data Protection Board and to affected people; penalties reach ₹250 crore. I did not verify the rules on cross-border transfer or retention periods: confirm with counsel.

## 6. What to take from your architecture

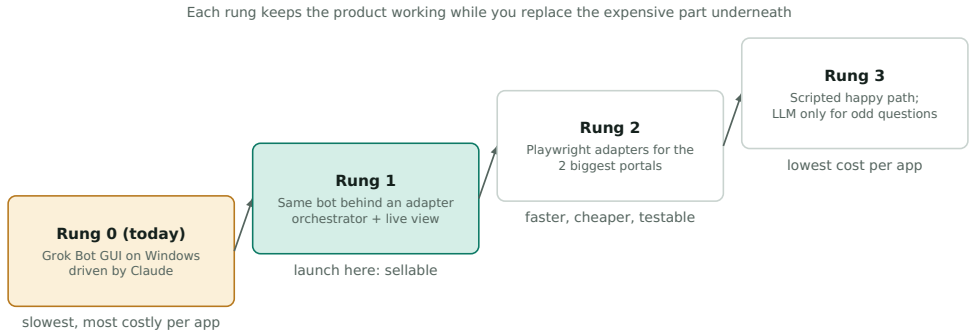

AutoJopps v2: my design with your ideas added: tier lanes, a canary bot, cells, and Grok Bot as the first adapter.

| Enhancement | Taken from your design | Why |
|---|---|---|
| Grok Bot as the first adapter | Your working bot | Launch on what works; replace one portal at a time. |
| Tier lanes | Primabot ratio per tier | Premium and Ultra get a planner lane and more runners; Basic uses |

| | | |
|---|---|---|
| | | the shared pool. |
| Canary bot per cell | System Stats Bot | Synthetic logins and portal health checks catch breakage before users do. |
| Cells | Windows Server 1..N | A cell is a server group the router fills up; one cell failing affects few users. |
| Windows-aware live view | Remote access to the Grok Bot computer | Signed single-use link to the Windows desktop for OTP and CAPTCHA while the bot is GUI-based. |
| Silo cell | Dedicated bundle for a user | Sell Ultra or enterprise with a dedicated VM and vault. |
| API keys, not subscriptions | (Replaces Claude installed) | Model gateway with API keys, per-tenant cost meter and a kill switch. |
| Self-service provisioning | (Fills a gap) | Payment triggers automatic assignment to a cell; no human sets up seats. |

### The automation ladder

Move up one rung at a time. Every rung is sellable.

## 7. Recommendation and open questions

1. Fix the licence question first: move model calls to the API under commercial terms, and check Grok Bot's terms for use inside a paid service.
2. Build the control plane (identity, entitlements, orchestrator, live view) around your bot for 2 portals. That is a real SaaS in a few weeks.
3. Replace the shared-desktop model with one fresh VM or browser context per run before you onboard strangers.
4. Track cost per application from the first user.

### Questions that change the answer

- Is each Windows server and Grok Bot “computer” dedicated to one customer or shared by many?
- Are the Claude and Grok Bot subscriptions yours, or does each customer bring their own?
- Where are the servers hosted (cloud region, or machines you own)?
- Does Grok Bot have an API or command line, or is it GUI only?
- Does Claude computer use work on your Windows Server setup?

## Sources

- Anthropic Consumer Terms
- Anthropic Commercial Terms
- Digital Personal Data Protection Act, 2023 (MeitY)

Checked 28 October 2026. Exchange rate ₹95.105 per USD. Net revenue assumes 18% GST included in the price and about 2% gateway fee. Not legal advice.
